### Chapter 1

# Subconstituent Algebra of a Graph

#### Wednesday, January 20, 1993

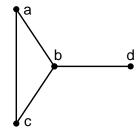

A graph (undirected, without loops or multiple edges) is a pair  $\Gamma=(X,E),$  where

$$X = \text{finite set (of vertices)}$$
 (1.1)

$$E = \text{set of (distinct) 2-element subsets of } X \ (= \text{edges of }) \ \Gamma.$$
 (1.2)

vertices x and  $y \in X$  are adjacent if and only if  $xy \in E$ .

**Example 1.1.** Let  $\Gamma$  be a graph.  $X = \{a, b, c, d\}, E = \{ab, ac, bc, bd\}.$ 

Set n = |X|, the order of  $\Gamma$ .

Pick a field K (=  $\mathbb{R}$  or  $\mathbb{C}$ ). Then  $\mathrm{Mat}_X(K)$  denotes the K algebra of all  $n \times n$  matrices with entries in K. (rows and columns are indexed by X)

Adjacency matrix  $A \in \operatorname{Mat}_X(K)$  is defined by

$$A_{xy} = \begin{cases} 1 & \text{if } xy \in E \\ 0 & \text{else} \end{cases}$$
 (1.3)

**Example 1.2.** Let a, b, c, d be labels of rows and columns. Then

$$A = b \begin{pmatrix} a & b & c & d \\ a & 0 & 1 & 1 & 0 \\ 1 & 0 & 1 & 1 \\ c & 1 & 1 & 0 & 0 \\ d & 0 & 1 & 0 & 0 \end{pmatrix}$$

The subalgebra M of  $\mathrm{Mat}_X(K)$  generated by A is called the Bose-Mesner algebra of  $\Gamma.$ 

Set  $V = K^n$ , the set of *n*-dimensional column vectors, the coordinates are indexed by X.

Let  $\langle \ , \ \rangle$  denote the Hermitean inner product:

$$\langle u,v\rangle = u^\top \cdot v \quad (u,v \in V)$$

V with  $\langle , \rangle$  is the standard module of  $\Gamma$ .

M acts on V: For every  $x \in X$ , write

$$\hat{x} = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}$$

where 1 is at the x position.

Then

$$A\hat{x} = \sum_{y \in X, xy \in E} \hat{y}.$$

Since A is a real symmetrix matrix,

$$V = V_0 + V_1 + \dots + V_r \quad \text{ some } r \in \mathbb{Z}^{\geq 0},$$

the orthogonal direct sum of maximal A-eigenspaces.

Let  $E_i \in \operatorname{Mat}_X(K)$  denote the orthogonal projection,

$$E_i: V \longrightarrow V_i$$
.

Then  $E_0, \dots, E_r$  are the primitive idempotents of M.

$$M = \operatorname{Span}_K(E_0, \dots, E_r),$$

$$E_i E_j = \delta_{ij} E_i \quad \text{for all} \ \ i,j, \quad E_0 + \dots + E_r = I.$$

Let  $\theta_i$  denote the eigenvalue of A for  $V_i$  in  $\mathbb{R}$ . Without loss of generality we may assume that

$$\theta_0 > \theta_1 > \dots > \theta_r$$
.

Let

 $m_i = \text{the multiplicity of } \theta_i = \text{dim} V_i = \text{rank} E_i.$ 

Set

$$\operatorname{Spec}(\Gamma) = \begin{pmatrix} \theta_0, & \theta_1, & \cdots, & \theta_r \\ m_0, & m_1, & \cdots, & m_r \end{pmatrix}.$$

**Problem.** What can we say about  $\Gamma$  when  $Spec(\Gamma)$  is given?

The following Lemma 1.1, is an example of Problem.

For every  $x \in X$ ,

$$k(x) \equiv \text{ valency of } x \equiv \text{ degree of } x \equiv |\{y \mid y \in X, xy \in E\}|.$$

**Definition 1.1.** The graph  $\Gamma$  is regular of valency k if k = k(x) for every  $x \in X$ .

Lemma 1.1. With the above notation,

- $(i)\ \theta_0 \leq \max\{k(x) \mid x \in X\} = k^{\max}.$
- (ii) If  $\Gamma$  is regular of valency k, then  $\theta_0 = k$ .

Proof.

(i) Without loss of generality we may assume that  $\theta_0 > 0$ , else done. Let  $v := \sum_{x \in X} \alpha_x \hat{x}$  denote the eivenvector for  $\theta_0$ .

Pick  $x \in X$  with  $|\alpha_x|$  maximal. Then  $|\alpha_x| \neq 0$ .

Since  $Av = \theta_0 v$ ,

$$\theta_0 \alpha_x = \sum_{y \in X, xy \in E} \alpha_y.$$

So,

$$\theta_0|\alpha_x| = |\theta_0\alpha_x| \leq \sum_{y \in X, xy \in E} |\alpha_y| \leq k(x)|\alpha_x| \leq k^{\max}|\alpha_x|.$$

(ii) All 1's vector  $v = \sum_{x \in X} \hat{x}$  satisfies Av = kv.

Subconstituent Algebra

Let  $x, y \in X$  and  $\ell \in \mathbb{Z}^{\geq 0}$ .

**Definition 1.2.** A path of length  $\ell$  connecting x, y is a sequence

$$x = x_0, x_1, \dots, x_{\ell} = y, \quad x_i \in X, \ 0 \le i \le \ell$$

such that  $x_i x_{i+1} \in E$  for  $0 \le i \le \ell - 1$ .

**Definition 1.3.** The distance  $\partial(x,y)$  is the length of a shortest path connecting x and y.

$$\partial(x,y) \in \mathbb{Z}^{\geq 0} \cup \{\infty\}.$$

**Definition 1.4.** The graph  $\Gamma$  is connected if and only if  $\partial(x,y) < \infty$  for all  $x,y \in X$ .

From now on, assume that  $\Gamma$  is connected with  $|X| \geq 2$ .

Set

$$d_{\Gamma} = d = \max\{\partial(x, y) \mid x, y \in X\} \equiv \text{the diameter of } \Gamma.$$

Fix a 'base' vertex  $x \in X$ .

#### Definition 1.5.

$$d(x) =$$
the diameter with respect to  $x = \max\{\partial(x,y) \mid y \in X\} \le d$ .

Observe that

$$V = V_0^* + V_1^* + \dots + V_{d(x)}^*$$
 (orthogonal direct sum),

where

$$V_i^* = \operatorname{Span}_K(\hat{y} \mid \partial(x,y) = i) \equiv V_i * (x)$$

and  $V_i^* = V_i^*(x)$  is called the *i*-the subconstituent with respect to x.

Let  $E_i^* = E_i^*(x)$  denote the orthogonal projection

$$E_i^*: V \longrightarrow V_i^*(x).$$

View  $E_i^*(x) \in \operatorname{Mat}_X(K)$ . So,  $E_i^*(x)$  is diagonal with yy entry

$$(E_i^*(x))_{yy} = \begin{cases} 1 & \text{if } \partial(x,y) = i \\ 0 & \text{else,} \end{cases} \quad \text{for } y \in X.$$

Set

$$M^*=M^*(x)\equiv \mathrm{Span}_K(E_0^*(x),\dots,E_{d(x)}^*(x)).$$

Then  $M^*(x)$  is a commutative subalgebra of  $\mathrm{Mat}_X(K)$  and is calle the dual Bose-Mesner algebra with respect to x.

**Definition 1.6** (Subconstituent Algebra). Let  $\Gamma = (X, E), x, M, M^*(x)$  be as above. Let T = T(x) denote the subalgebra of  $\operatorname{Mat}_X(K)$  generated by M and  $M^*(x)$ . T is the *subconstituent algebra* of  $\Gamma$  with respect to x.

**Definition 1.7.** A T-module is any subspace  $W \subset V$  such that  $aw \in W$  for all  $a \in T$  and  $w \in W$ .

T-module W is *irreducible* if and only if  $W \neq 0$  and W does not properly contain a nonzero T-module.

For any  $a \in \operatorname{Mat}_X(K)$ , let  $a^*$  denbote the conjugate transpose of a.

Observe that

$$\langle au, v \rangle = \langle u, a^*v \rangle$$
 for all  $a \in \operatorname{Mat}_X(K)$ , and for all  $u, v \in V$ .

**Lemma 1.2.** Let  $\Gamma = (X, E)$ ,  $x \in X$  and  $T \equiv T(x)$  be as above.

- (i) If  $a \in T$ , then  $a^* \in T$ .
- (ii) For any T-module  $W \subset V$ ,

$$W^{\perp} := \{ v \in V \mid \langle w, v \rangle = 0, \text{ for all } w \in W \}$$

is a T-module.

(iii) V decomposes as an orthogonal direct sum of irreducible T-modules.

Proof.

(i) It is becase T is generated by symmetric real matrices

$$A, E_0^*(x), E_1^*(x), \dots, E_{d(x)(x)}^*.$$

(ii) Pick  $v \in W^{\perp}$  and  $a \in T$ , it suffices to show that  $av \in W^{\perp}$ . For all  $w \in W$ ,

$$\langle w, av \rangle = \langle a^*w, v \rangle = 0$$

as  $a^* \in T$ .

(iii) This is proved by the induction on the dimension of T-modules. If W is an irreducible T-module of V, then

$$V = W + W^{\perp}$$
 (orthogonal direct sum).

**Problem.** What does the structure of the T(x)-module tell us about  $\Gamma$ ?

Study those  $\Gamma$  whose modules take 'simple' form. The  $\Gamma$ 's involved are highly regular.

Remark.

- 1. The subconstituent algebra T is semisimple as the left regular representation of T is completely reducible. See Curtis-Reiner 25.2 (?).
- 2. The inner product  $\langle a, b \rangle_T = \operatorname{tr}(a^{\top}\overline{b})$  is nondegenerate on T.
- 3. In general,
  - T: Semisimple and Artinian  $\Leftrightarrow$  T: Artinian with J(T) = 0

 $\Leftarrow T$ : Artinian with nonzero nilpotent element

 $\Leftarrow T \subset \operatorname{Mat}_X(K)$  such that for all  $a \in T$  is normal.

### Chapter 2

### Perron-Frobenius Theorem

#### Friday, January 22, 1993

In this lecture we use the Perron Frobenius theory of nonnegative matrices to obtain information on eigenvalues of a graph.

Let  $K = \mathbb{R}$ . For  $n \in \mathbb{Z}^{>0}$ , pick a symmetrix matrix  $C \in \operatorname{Mat}_n(\mathbb{R})$ .

**Definition 2.1.** The matrix C is reducible if and only if there is a bipartition  $\{1,2,\ldots,n\}=X^+\cup X^-$  (disjoint union of nonempty sets) such that  $C_{ij}=0$  for all  $i\in X^+$ , and for all  $j\in X^-$ , and for all  $i\in X^-$ , and for all  $j\in X^+$ , i.e.,

$$C \sim \begin{pmatrix} * & O \\ O & * \end{pmatrix}$$
.

**Definition 2.2.** The matrix C is *bipartite* if and only if there is a bipartition  $\{1,2,\ldots,n\}=X^+\cup X^-$  (disjoint union of nonempty sets) such that  $C_{ij}=0$  for all  $i,j\in X^+$ , and for all  $i,j\in X^-$ , i.e.,

$$C \sim \begin{pmatrix} O & * \\ * & O \end{pmatrix}$$
.

Note.

1. If C is bipatite, for every eigenvalue  $\theta$  of C,  $-\theta$  is an eigenvalue of C such that  $\operatorname{mult}(\theta) = \operatorname{mult}(-\theta)$ .

Indeed, let  $C = \begin{pmatrix} O & A \\ B & O \end{pmatrix}$ ,

$$\begin{pmatrix} O & A \\ B & O \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \theta \begin{pmatrix} x \\ y \end{pmatrix} \Leftrightarrow \begin{pmatrix} O & A \\ B & O \end{pmatrix} \begin{pmatrix} x \\ -y \end{pmatrix} = -\theta \begin{pmatrix} x \\ -y \end{pmatrix},$$

where  $Ay = \theta x$  and  $Bx = \theta y$ .

- 2. If C is bipartite,  $C^2$  is reducible.
- 3. The matrix C is irreducible and  $C^2$  is reducible, if  $C_{ij} \geq 0$  for all i,j and C is reducible. (Exercise)

Remark. Note 1. Even if C is not symmetric

$$\begin{pmatrix} O & A \\ B & O \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \theta \begin{pmatrix} x \\ y \end{pmatrix} \Leftrightarrow \begin{pmatrix} O & A \\ B & O \end{pmatrix} \begin{pmatrix} x \\ -y \end{pmatrix} = -\theta \begin{pmatrix} x \\ -y \end{pmatrix}$$

holds. So the geometrix multiplicities coincide. How about the algebraic multiplicities?

Note 3. Set  $x \sim y$  if and only if  $C_{xy} > 0$ . So the graph may have loops. Then

$$(C^2)_{xy} > 0 \Leftrightarrow \text{ if there exists } z \in X \text{ such that } x \sim z \sim y.$$

Note that C is irreducible if and only if  $\Gamma(C)$  is connected. Let

$$X^{+} = \{ y \mid \text{there is a path of even length from } x \text{ to } y \}$$
 (2.1)

$$X^{-} = \{y \mid \text{there is no path of even length from } x \text{ to } y\} \neq \emptyset.$$
 (2.2)

If there is an edge  $y \sim z$  in  $X^+$  and  $w \in X^-$ . Then there would be a path from x to y of even length. So  $e(X^+, X^+) = e(X^-, X^-) = 0$ ..

**Theorem 2.1** (Perron-Frobenius). Given a matrix C in  $\operatorname{Mat}_n(\mathbb{R})$  such that

- (a) C is symmetric.
- (b) C is irreducible.
- (c)  $C_{ij} \geq 0$  for all i, j.

Let  $\theta_0$  be the maximal eigenvalue of C with eigenspace  $V_0 \subseteq \mathbb{R}^n$ , and let  $\theta_r$  be the maximal eigenvalue of C with eigenspace  $V_r \subseteq \mathbb{R}^n$ . Then the following hold.

$$(i) \ \textit{Suppose} \ 0 \neq v = \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_n \end{pmatrix} \in V_0. \ \textit{Then} \ \alpha_0 > 0 \ \textit{for all} \ i, \ \textit{or} \ \alpha_i < 0 \ \textit{for all} \ i.$$

- $(ii) \dim V_0 = 1.$
- (iii)  $\theta_r \geq -\theta_0$ .
- (iv)  $\theta_r = \theta_0$  if and only if C is bipartite.

First, we prove the following lemma.

**Lemma 2.1.** Let  $\langle \ , \ \rangle$  be the dot product in  $V = \mathbb{R}^n$ . Pick a symmetric matrix  $B \in \operatorname{Mat}_n(\mathbb{R})$ . Suppose all eigenvalues of B are nonnegative. (i.e., B is positive semidefinite.) Then there exist vectors  $v_1, v_2, \dots, v_n \in V$  such that  $B_{ij} = \langle v_i, v_j \rangle$  for  $(1 \leq i, j \leq n)$ .

*Proof.* By elementary linear algebra, there exists an orthonormal basis  $w_1, w_2, \ldots, w_n$  of V consisting of eigenvectors of B. Set the i-th column of P is  $w_i$  and  $D = \operatorname{diag}(\theta_1, \ldots, \theta_n)$ . Then  $P^\top P = I$  and BP = PD.

Hence,

$$B = PDP^{-1} = PDP^{\top} = QQ^{\top},$$

where

$$Q = P \cdot \mathrm{diag}(\sqrt{\theta_1}, \sqrt{\theta_2}, \dots, \sqrt{\theta_n}) \in \mathrm{Mat}_n(\mathbb{R}).$$

Now, let  $v_i$  be the *i*-th column of  $Q^{\top}$ . Then

$$B_{ij} = v_i^\top \cdot v_j^- = \langle v_i, v_j \rangle.$$

Now we start the proof of Theorem 2.1.

Proof of Theorem 2.1(i)

Let  $\langle , \rangle$  denote the dot product on  $V = \mathbb{R}^n$ . Set

$$B = \theta I - C \tag{2.3}$$

= symmetric matrix with eigenvalues 
$$\theta_0 - \theta_i \ge 0$$
 (2.4)

$$=(\langle v_i,v_j\rangle)_{1\leq i,j\leq n} \tag{2.5}$$

with the same  $v_1,\dots,v_n\in V$  by Lemma 2.1.

Observe:  $\sum_{i=1}^{n} \alpha_i v_i = 0$ .

Pf.

$$\|\sum_{i=1}^{n} \alpha_i v_i\|^2 = \langle \sum_{i=1}^{n} \alpha_i v_i, \sum_{i=1}^{n} \alpha_i v_i \rangle$$

$$(2.6)$$

$$= \begin{pmatrix} \alpha_1 & \dots & \alpha_n \end{pmatrix} B \begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{pmatrix} \tag{2.7}$$

$$= v^{\top} B v \tag{2.8}$$

$$=0, (2.9)$$

since  $Bv = (\theta_0 I - C)v = 0$ .

Now set

s =the number of indicesi, where  $\alpha_i > 0$ .

Replacing v by -v if necessary, without loss of generality we may assume that  $s \ge 1$ . We want to show s = n.

Assume s < n. Without loss of generality, we may assume that  $\alpha_i > 0$  for  $1 \le s \le s$  and  $\alpha_i = 0$  for  $s+1 \le i \le n$ . Set

$$\rho = \alpha_1 v_1 + \dots + \alpha_s v_s = -\alpha_{s+1} v_{s+1} - \dots - \alpha_n v_n.$$

Then, for  $i = 1, \dots, s$ ,

$$\langle v_i, \rho \rangle = \sum_{j=s+1}^n -\alpha_j \langle v_i, v_j \rangle \quad (\langle v_i, v_j \rangle = B_{ij}, B = \theta_0 I - C) \tag{2.10}$$

$$= \sum_{j=s+1}^{n} (-\alpha_{ij})(-C_{ij}) \tag{2.11}$$

$$\leq 0. \tag{2.12}$$

Hence

$$0 \leq \langle \rho, \rho \rangle = \sum_{i=1}^s \alpha_i \langle v_i, \rho \rangle \leq 0,$$

as  $\alpha>0$  and  $\langle v_i,\rho\rangle\leq 0$ . Thus, we have  $\langle,\rho,\rho\rangle=0$  and  $\rho=0$ . For  $j=s+1,\ldots,n,$ 

$$0 = \langle \rho, v_j \rangle = \sum_{i=1}^s \alpha_i \langle v_i, v_j \rangle \le 0,$$

as  $\langle v_i, v_j \rangle = -C_{ij}$ .

Therefore,

$$0 = \langle v_i, v_j \rangle = -C_{ij} \text{ for } 1 \le i, \le s, \ s+1 \le j \le n.$$

Since C is symmetric,

$$C = \begin{pmatrix} * & O \\ O & * \end{pmatrix}$$

Thus C is reducible, which is not the case. Hence s = n.

Proof of Theorem 2.1 (ii).

Suppose dim  $V_0 \ge 2$ . Then,

$$\dim \left( V_0 \cap \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}^{\perp} \right) \geq 1.$$

So, there is a vector

$$0 \neq v = \begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{pmatrix} \in V_0$$

with  $\alpha_1 = 0$ . This contradicts 1.

Now pick

$$0 \neq w = \begin{pmatrix} \beta_1 \\ \vdots \\ \beta_n \end{pmatrix} \in V_r.$$

Proof of Theorem 2.1 (iii).

Suppose  $\theta_r < -\theta_0$ . Since the eigenvalues of  $C^2$  are the squares of those of C,  $\theta_r^2$  is the maximal eigenvalue of  $C^2$ .

Also we have  $C^2w = \theta_r^2w$ .

Observe that  $C^2$  is irreducible. (As otherwise, C is bipartite by Note 3, and we must have  $\theta_r=-\theta_0$ .) Therefore,  $\beta_i>0$  for all i or  $\beta_i<0$  for all i. We have

$$\langle v, w \rangle = \sum_{i=1}^{n} \alpha_i \beta_i \neq 0.$$

This is a contradiction, as  $V_0 \perp V_r$ .

Proof of Theorem 2.1 (iv)

 $\Rightarrow$ : Let  $\theta_r = -\theta_0$ . Then  $\theta = \theta_1^2 = \theta_0^2$  is the maximal eigenvalue of  $C^2$ , and v and w are linearly independent eigenvalues for  $\theta$  for  $C^2$ . Hence, for  $C^2$ , mult $(\theta) \geq 2$ .

Thus by 2,  $C^2$  must be reducible. Therefore, C is bipartite by Note 3.

 $\Leftarrow$ : This is Note 1.  $\square$ 

Let  $\Gamma = (X, E)$  be any graph.

**Definition 2.3.**  $\Gamma$  is said to be *bipartite* if the adjacency matrix A is bipartite. That is, X can be written as a disjoint union of  $X^+$  and  $X^-$  such that  $X^+, X^-$  contain no edges of  $\Gamma$ .

Corollary 2.1. For any (connected) graph  $\Gamma$  with

$$\operatorname{Spec}(\Gamma) = \begin{pmatrix} \theta_0 & \theta_1 & \cdots & \theta_r \\ m_1 & m_1 & \cdots & m_r \end{pmatrix} \quad with \ \ \theta_0 > \theta_1 > \cdots > \theta_r.$$

Let  $V_i$  be the eigenspace of  $\theta_i$ . Then the following holds.

- 2.  $m_0 = 1$ .
- 3.  $\theta_r \geq -\theta_0$  if and only if  $\Gamma$  is bipartite. In this case,

$$-\theta_i = \theta_{r-i} \ and \ m_i = m_{r-i} \quad (0 \leq i \leq r)$$

*Proof.* This is a direct consequences of Theorem 2.1 and Note 3.  $\Box$ 

### Chapter 3

# Cayley Graphs

Monday, January 25, 1993

Given graphs  $\Gamma = (X, E)$  and  $\Gamma' = (X', E')$ .

**Definition 3.1.** A map  $\sigma: X \to X'$  is an *isomorphism*\index{isomorphism of graphs whenever;

- i.  $\sigma$  is one-to-one and onto,
- ii.  $xy \in E$  if and only if  $\sigma x \sigma y \in E'$  for all  $x, y \in X$ .

We do not distinguish between isomorphic graphs.

**Definition 3.2.** Suppose  $\Gamma = \Gamma'$ . Above isomorphism  $\sigma$  is called an *automorphism* of  $\Gamma$ . Then set  $\operatorname{Aut}(\Gamma)$  of all automorphisms of  $\Gamma$  becomes a finite group under composition.

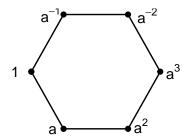

**Definition 3.3.** If  $Aut(\Gamma)$  acts transitive on X,  $\Gamma$  is called *vertex transitive*.

**Example 3.1.** A Cayley graphs:

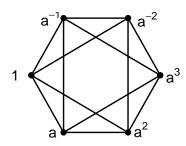

**Definition 3.4** (Cayley Graphs). Let G be any finite group, and  $\Delta$  any generating set for G such that  $1_G \notin \Delta$  and  $g \in \Delta \to g^{-1} \in \Delta$ . Then Cayley graph  $\Gamma = \Gamma(G, \Delta)$  is defined on the vetex set X = G with the edge set E define by the following.

$$E = \{(h_1, h_2) \mid h_1, h_2 \in G, h_1^{-1}h_2 \in \Delta\} = \{(h, hg) \mid h \in G, g \in \Delta\}$$

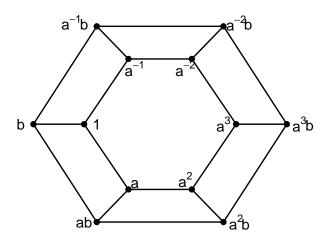

**Example 3.2.**  $G = \langle a \mid a^6 = 1 \rangle, \Delta = \{a, a^{-1}\}.$ 

**Example 3.3.**  $G = \langle a \mid a^6 = 1 \rangle, \Delta = \{a, a^{-1}, a^2, a^{-2}\}.$ 

**Example 3.4.**  $G = \langle a, b \mid a^6 = 1, b^2, ab = ba \rangle, \Delta = \{a, a^{-1}, b\}.$ 

Remark.  $\operatorname{Aut}(\Gamma) \simeq D_6 \times \mathbb{Z}_2$  contains two regular subgroups isomorphic to  $D_6$  and  $\mathbb{Z}_5 \times \mathbb{Z}_2$  and  $\Gamma$  is obtained as Cayley graphs in two ways.

Cayley graphs are vertex transitive, indeed.

Theorem 3.1. The following hold.

(i) For any Cayley graph  $\Gamma = \Gamma(G, \Delta)$ , the map

$$G \to \operatorname{Aut}(\Gamma) \ (g \mapsto \hat{g})$$

is an injective homomorphism of groups, where

$$\hat{g}(x) = gx \quad \textit{for all } g \in G \textit{ and for all } x \in X (=G).$$

Also, the image  $\hat{G}$  is regular on X. i.e., the image  $\hat{G}$  acts transitively on X with trivial vertex stabilizers.

(ii) For any graph  $\Gamma = (X, E)$ , suppose there exists a subgroup  $G \subseteq \operatorname{Aut}(\Gamma)$  that is regular on X. Pick  $x \in X$ , and let

$$\Delta = \{ g \in G \mid \langle x, g(x) \in E \}.$$

Then  $1 \notin \Delta$ ,  $g \in \Delta \to g^{-1} \in \Delta$ , and  $\Delta$  generates G. Moreover,  $\Gamma \simeq \Gamma(G, \Delta)$ .

*Proof.* (i) Let  $g \in G$ . We want to show that  $\hat{g} \in \text{Aut}(\Gamma)$ . Let  $h_1, h_2 \in X = G$ . Then,

$$(h_1, h_2) \in E \to h_1^{-1} h_2 \in \Delta$$
 (3.1)

$$\to (gh_1)^{-1}(gh_2) \in \Delta \tag{3.2}$$

$$\to (gh_1, gh_2) \in E \tag{3.3}$$

$$\to (\hat{g}(h_1), \hat{g}(h_2)) \in E. \tag{3.4}$$

Hence,  $\hat{g} \in \text{Aut}(\Gamma)$ .

Observe:  $g \mapsto \hat{g}$  is a homomorphism of groups:

$$\widehat{1}_G = 1, \ \widehat{g_1 g_2} = \widehat{g_1 g_2}.$$

Observe:  $g \mapsto \hat{g}$  is one-to-one:

$$\widehat{g_1} = \widehat{g_2} \to g_1 = \widehat{g_1}(1_G) = \widehat{g_2}(1_G) = g_2.$$

Observe:  $\hat{G}$  is regular on X: Clear by construction.

(ii)  $1_G \notin \Delta$ : Since  $\Gamma$  has not loops,  $(x, 1_G x) \notin E$ .

 $q \in \Delta \to g^{-1} \in \Delta$ :

$$q \in \Delta \to (x, q(x)) \in E \to E \ni (q^{-1}(x), q^{-1}(q(x))) = (q^{-1}(x), x).$$

 $\Delta$  generates G: Suppose  $\langle \Delta \subsetneq G$ . Let  $\hat{X} = \{g(x) \mid g \in \langle \Delta \rangle\} \subsetneq X$ .  $(\hat{X} \subsetneq X \text{ as } G \text{ acts regularly on } X.)$ 

Since  $\Gamma$  is connected, there exists  $y \in \hat{X}$  and  $z \in X$   $\hat{X}$  with  $yz \in E$ .

Let 
$$y = g(x), g \in \langle \Delta \rangle, z \in h(x), h \in G \langle \Delta \rangle$$
. Then

$$(y,z) = (q(x),h(x)) \in E \to (x,q^{-1}h(x)) \in E \to q^{-1}h \in \langle \Delta \rangle \to h \in \langle \Delta \rangle.$$

This is a contradition. Therefore,  $\Delta$  generates G.

Let  $\Gamma' = (X', E')$  denote  $\Gamma(G, \Delta)$ . We shall show that

$$\theta: X' \to X \ (g \mapsto g(x))$$

is an isomorphism of graphs.

 $\theta$  is one-to-one: For  $h_1, h_2 \in X' = G$ ,

$$\theta(h_1) = \theta(h_2) \to h_1(x) = h_2(x) \to h_2^{-1}h_1(x) = x \to h_2^{-1}h_1 \in \operatorname{Stab}_G(x) = \{1_G\} \to h_1 = h_2.$$

$$(\operatorname{Stab}_G = \{ g \in G \mid g(x) = x \}.)$$

 $\theta$  is onto: Since G is transitive,

$$X = \{g(x) \mid g \in G\} = \theta(X') = \theta(G).$$

 $\theta$  respects adjacency: For  $h_1, h_2 \in X' = G$ ,

$$(h_1,h_2)\in E' \leftrightarrow h_1^{-1}h_2\in \Delta \leftrightarrow (x,h_1^{-1}h_2(x))\in E \leftrightarrow (h_1(x),h_2(x))\in E \leftrightarrow (\theta(h_1),\theta(h_2))\in E.$$

Therefore  $\theta$  is an isomorphism between graphs  $\Gamma(G, \Delta)$  and  $\Gamma(X, E)$ .

How to compute the eigenvalues of the Cayley graph of and abelian group.

Let G be any finite abelian group. Let  $\mathbb{C}^*$  be the multiplicative group on  $\mathbb{C}$   $\{0\}$ .

**Definition 3.5.** A (linear) *G*-character is any group homomorphism  $\theta: G \to \mathbb{C}^*$ 

**Example 3.5.**  $G = \langle a \mid a^3 = 1 \rangle$  has three characters,  $\theta_0, \theta_1, \theta_2$ .

$$\begin{array}{c|cccc} \theta_i(a^j) & 1 & a & a^2 \\ \hline \theta_0 & 1 & 1 & 1 \\ \theta_1 & 1 & \omega & \omega^2 \\ \theta_2 & 1 & \omega^2 & \omega \end{array}, \quad \text{with } \omega = \frac{-1 + \sqrt{-3}}{2}.$$

Here  $\omega$  is a primitive cube root pf q in  $\mathbb{C}^*$ , i.e.,  $1 + \omega + \omega^2 = 0$ .

For arbitrary group G, let X(G) be the set of all characters of G.

Observe: For  $\theta_1, \theta_2 \in X(G)$ , one can define product  $\ \_1 \ \_2$ :

$$\theta_1\theta_2(g) = \theta_1(g)\theta_2(g)$$
 for all  $g \in G$ .

Then  $\theta_1\theta_2 \in X(G)$ .

Observe: X(G) with this product is an (abelian) group.

**Lemma 3.1.** The groups G and X(G) are isomorphic for all finite abelian groups G.

*Proof.* G is a direct sum of cyclic groups;

$$G = G_1 \oplus G_2 \oplus \cdots \oplus G_m, \quad \text{where} \ \ G_i = \langle a_i \mid a_i^{d_i} = 1 \rangle \quad (1 \leq i \leq m).$$

Pick any alement  $\omega_i$  of order  $d_i$  in  $\mathbb{C}^*$ , i.e., a primitive  $d_i$ -the root of 1. Define

$$\theta_i: G \to \mathbb{C}^* \quad (a_1^{\varepsilon_1} \cdots a_m^{\varepsilon_m} \mapsto \omega_i^{\varepsilon_i} \quad \text{where} \ \ 0 \le \varepsilon_i < d_i, 1 \le i \le m).$$

Then  $\theta_i \in X(G)$ . (Exercise)

Claim: There exists an isomorphism of groups  $G \to X(G)$  that sends  $a_i$  to  $\theta_i$ .

Observe:  $\theta_i^{d_i} = 1$ . For every  $g = a_1^{\varepsilon_1} \cdots a_m^{\varepsilon_m} \in G$ ,

$$\theta_i^{d_i}(g) = (\theta_i(g))^{d_i} = (\omega_i^{\varepsilon_i})^{d_i} = (\omega_i^{d_i})^{\varepsilon_i} = 1.$$

Observe: If  $\theta_1^{\varepsilon_1}\theta_2^{\varepsilon_2}\cdots\theta_m^{\varepsilon_m}=1$  for some  $0\leq \varepsilon_i < d_i, 1\leq i\leq m$ . Then  $\varepsilon_1=\varepsilon_2=\cdots=\varepsilon_m=0$ .

 $\begin{array}{l} \textit{Pf. } 1 = \theta_1^{\varepsilon_1} \theta_2^{\varepsilon_2} \cdots \theta_m^{\varepsilon_m}(a_i) = \omega_i^{\varepsilon_i}, \\ \textit{Since } \omega_i \text{ is a primitive } d_i\text{-th root of } 1, \, \varepsilon_i = 0 \text{ for } 1 < i < m. \end{array}$ 

Observe:  $\theta_1,\dots,\theta_m$  generate X(G). Pick  $\theta\in X(G)$ . Since  $a_i^{d_i}=1,\,1=\theta(a_i^{d_i})=\theta(a_i)^{d_i}$ .

Hence  $\theta(a_i) = \omega^{\varepsilon_i}$  for some  $\varepsilon_i$  with  $0 \le \varepsilon_i < d_i$ .

Now  $\theta = \theta_1^{\varepsilon_1} \cdots \theta_m^{\varepsilon_m}$ , since these are both equal to  $\omega_i^{\varepsilon_i}$  at  $a_i$  for  $1 \le i \le m$ .

Therefore,

$$G \to X(G) \quad (a_i \mapsto \theta_i)$$

is an isomorphism of groups.

Note. The correspondence above is clearly a group homomorphism.

### Chapter 4

# Examples

Wednesday, January 27, 1993

**Theorem 4.1.** Given a Cayley graph  $\Gamma = \Gamma(G, \Delta)$ . View the standard module  $V \equiv \mathbb{C}G$  (the group algebra), so

$$\left\langle \sum_{g \in G} \alpha_g g, \; \sum_{g \in G} \beta_g g \right\rangle = \sum_{g \in G} \alpha_g \overline{\beta_g}, \quad \text{with } \alpha_g, \beta_g \in \mathbb{C}.$$

For any  $\theta \in X(G)$ , write

$$\hat{\theta} = \sum_{g \in G} \theta(g^{-1})g.$$

Then the following hold.

- $\begin{array}{l} (i)\ \langle \hat{\theta_1}, \hat{\theta_2} \rangle = |G|\ if\ \theta_1 = \theta_2\ and\ 0\ othewise\ for\ \theta_1, \theta_2 \in X(G).\ In\ particular, \\ \{\hat{\theta}\mid \theta \in X(G)\}\ forms\ a\ basis\ for\ V. \end{array}$
- (ii)  $A\hat{\theta} = \Delta_{\theta}\hat{\theta}$  for  $\theta \in X(G)$ , where A is the adjacency matrix and

$$\Delta_\theta = \sum_{g \in \Delta} \theta(g).$$

In particular, the eigenvalues of  $\Gamma$  are precisely

$$\Delta_{\theta} \mid \theta \in X(G) \}.$$

Proof.

(i) Claim: For every  $\theta \in X(G)$ , let

$$s:=\sum_{g\in G}\theta(g^{-1})=\begin{cases} |G| & \text{if } \theta=1\\ 0 & \text{if } \theta\neq 1. \end{cases}$$

*Pf.* Clear if  $\theta = 1$ .

Let  $\theta \neq 1$ . Then  $\theta(h) \neq 1$  for some  $h \in G$ .

$$s\cdot\theta(h) = \left(\sum_{g\in G}\theta(g^{-1})\right)\theta(h) = \sum_{g\in G}\theta(g^{-1}h) = \sum_{g'\in G}\theta(g'^{-1}) = s.$$

Since  $\theta(h) \neq 1$ , s = 0.

Claim.  $\theta(g^{-1}) = \overline{\theta(g)}$  for every  $\theta \in X(G)$  and every  $g \in G$ .

Since  $\theta(g) \in \mathbb{C}$  is a root of 1,

$$|\theta(g)|^2 = \theta(g)\overline{\theta(g)} = 1.$$

On the other hand, since  $\theta$  is a homomorphism,

$$\theta(g)\theta(g^{-1}) = \theta(1) = 1.$$

Hence  $\theta(g^1) = \overline{\theta(g)}$ .

Now

$$\langle \widehat{\theta_1}, \widehat{\theta_2} \rangle = \sum_{g \in G} \theta_1(g^{-1}) \overline{\theta_2(g^{-1})}$$

$$\tag{4.1}$$

$$= \sum_{g \in G} \theta_1(g^{-1})\theta_2(g)$$

$$= \sum_{g \in G} \theta_1\theta_2^{-1}(g^{-1})$$
(4.2)

$$= \sum_{g \in G} \theta_1 \theta_2^{-1}(g^{-1}) \tag{4.3}$$

$$= \begin{cases} |G| & \text{if} \quad \theta_1 \theta_2^{-1} = 1\\ 0 & \text{if} \quad \theta_1 \theta_2^{-1} \neq 1. \end{cases}$$
 (4.4)

Since |G|=|X(G)| by Lemma 3.1, and  $\widehat{\theta_i}$ 's are orthogonal nonzero elements in V, thet form a basis of V.

(ii) Let 
$$\Delta = \{g_1, \dots, g_r\}$$
. Then

$$A\hat{\theta} = A\left(\sum_{g \in G} \theta(g^{-1}g)\right) \tag{4.5}$$

$$= \sum_{g \in G} \theta(g^{-1})(gg_1 + \dots + gg_r) \quad (\Gamma(g) = \{gg_1, \dots, gg_r\})$$
 (4.6)

$$=\sum_{i=1}^r \left(\sum_{g\in G} \theta(g^{-1})(gg_i)\right) \tag{4.7}$$

$$= \sum_{i=1}^{r} \left( \sum_{g \in G} \theta(g_i g_i^{-1} g^{-1})(g g_i) \right)$$
 (4.8)

$$= \sum_{i=1}^{r} \left( \sum_{g \in G} \theta(g_i) \theta((gg_i)^{-1}) gg_i \right) \tag{4.9}$$

$$= \sum_{i=1}^{r} \theta(g_i) \sum_{h \in G} \theta(h^{-1})h \tag{4.10}$$

$$= \Delta_{\theta} \cdot \hat{\theta}. \tag{4.11}$$

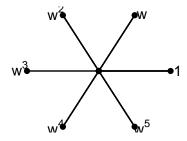

Since  $\{\hat{\theta} \mid \theta \in X(G)\}$  forms a basis, the eigenvalues of  $\Gamma$  are precisely,

$$\{\Delta_\theta \mid \theta \in X(G)\}.$$

This completes the proof.

**Example 4.1.** Let  $G = \langle a \mid a^6 = 1 \rangle$ , and  $\Delta = \{a, a^{-1}\}$ . Pick a primitive 6-th root of 1,  $\omega$ . Then

$$X(G) = \{\theta^i \mid 0 \leq i \leq 5\} \quad \text{such that} \quad \theta(a) = \omega, \; \omega + \omega^{-1} = 1.$$

$$\begin{array}{c|ccccc} \varphi \in X(G) & \varphi(a) & \Delta_{\varphi} = \theta(a) + \theta(a)^{-1} \\ \hline 1 & 1 & 2 \\ \theta & \omega & \omega + \omega^{-1} = 1 \\ \theta^2 & \omega^2 & -1 \\ \theta^3 & \omega^3 = -1 & -2 \\ \theta^4 & \omega^4 & -1 \\ \theta^5 & \omega^5 & 1 \\ \hline \end{array}$$

$$\operatorname{Spec}(\Gamma) = \begin{pmatrix} 2 & 1 & -1 & -2 \\ 1 & 2 & 2 & 1 \end{pmatrix}.$$

**Example 4.2.** D-cube, H(D, 2). Let

$$X = \{(a_1, \dots, a_D) \mid a_i \in \{1, -1\}, \ 1 \le i \le D\},\$$

 $E = \{xy \mid x,y \in X, \ x,y \text{: different in exactly one coordinate}\}.$ 

Also H(D,2) is a Cayley graph  $\Gamma(G,\Delta)$ , where

$$G = G_1 \oplus G_2 \oplus \cdots \oplus G_D$$
,

$$G_i = \langle a_i \mid a_i^2 = 1 \rangle, \quad \Delta = \{a_1, \dots, a_D\}.$$

**Homework**: The spectrum of H(D, 2) is

$$\begin{pmatrix} \theta_0 & \theta_1 & \cdots & \theta_D \\ m_0 & m_1 & \cdots & m_D \end{pmatrix},$$

where

$$\theta_i = D - 2i \quad (0 \leq i \leq D), \quad m_i = \binom{D}{i}.$$

Remark. Let  $\theta \in X(G)$ . Then  $\theta : X \to \{\pm 1\}$ . If

$$\nu(\theta) = |\{i \mid \theta(a_i) = -1\}|,$$

then  $\Delta_{\theta} = D - 2i$ . Since there are  $\binom{D}{i}$  such  $\theta$ , we have te assertion.

We want to compute the subconstituent algebra for H(D,2). First, we make a few observations about arbitrary graphd.

Let  $\Gamma=(X,E)$  be any graph, A, the adjacemcy matrix of  $\Gamma$ , and V, the standard module over  $K=\mathbb{C}$ .

Fix a base  $x \in X$ . Write  $E_i^* = E_i^*(x)$ , and

$$T \equiv T(x) =$$
the algebra generated by  $A, E_0^*, E_1^*, \dots$ 

**Definition 4.1.** Let W be any orreducible T-module ( $\subseteq V$ ). Then the endpoint  $r \equiv r(W)$  satisfied

$$r = \min\{i \mid E_i^* W \neq 0\}.$$

The diameter d = d(W) satisfied

$$d = |\{i \mid E_i^*W \neq 0\}| - 1.$$

Lemma 4.1. With the above notation, let W be an irreducible T-module. Then

(i) 
$$E_i^*AE_i^* = 0$$
 if  $|i-j| = 1$ ,  $\neq 0$  if  $|i-j| = 1$ ,  $0 \le i, j \le d(x)$ .

$$\begin{array}{l} (i)\ E_i^*AE_j^*=0\ \ if\ |i-j|=1, \quad \neq 0\ \ if\ |i-j|=1, \quad 0\leq i, j\leq d(x).\\ (ii)\ AE_j^*W\subseteq E_{j-1}^*W+E_j^*W+E_{j+1}^*W,\ 0\leq j\leq d(x).\ (E_i^*W=0\ \ if\ i< j\ or\ i>d(x).) \end{array}$$

$$(iv) E_i^* A E_i^* W \neq 0, if |i-j| = 1 \ (r \leq i, j \leq r+d)$$

Proof.

(i) Pick  $y \in X$  with  $\partial(x,y) = j$ . We want to find  $E_i^* A E_j^* \hat{y}$ . Note,

$$E_j^* \hat{y} = \begin{cases} 0 & \text{if } \partial(x.y) \neq j \\ \hat{y} & \text{if } \partial(x,y) = j. \end{cases}.$$

$$E_i^* A E_j^* \hat{y} = E_i^* A \hat{y} \tag{4.12}$$

$$=E_i^* \sum_{i} \hat{z} \tag{4.13}$$

$$= E_i^* \sum_{z \in X, yz \in E} \hat{z}$$

$$= \sum_{z \in X, yz \in E, \partial(x,z) = i} \hat{z}$$

$$(4.13)$$

$$=0 \ \ {\rm if} \ \ |i-j|>1 \ {\rm by \ triangle \ inequality}. \eqno(4.15)$$

If |i-j|=1, there exist  $y,y'\in X$  such that  $\partial(x,y)=j,\ \partial(x,y')=i,\ yy'\in E$ by connectivity of  $\Gamma$ . Hence (\*) contains  $\widehat{y'}$  and  $* \neq 0$ .

(ii) We have

$$AE_{j}^{*}W = \left(\sum_{i=0}^{d(x)} E_{i}^{*}\right) AE_{j}^{*}W \tag{4.16}$$

$$=E_{j-1}^*AE_j^*W+E_j^*AE_j^*W+E_{j+1}^*AE_j^*W \hspace{1cm} (4.17)$$

$$\subseteq E_{i-1}^*W + E_i^*W + E_{i+1}^*W.$$
 (4.18)

(iii) Suppose  $E_i^*W = 0$  for some j  $(r \le j \le r + d)$ . Then r < j by the definition of r. Set

$$\tilde{W} = E_i^*W + E_{r+1}^*W + \dots + E_{j-1}^*W.$$

Observe  $0 \subseteq \tilde{W} \subseteq W$ . Also  $A\tilde{W} \subseteq \tilde{W}$  by (ii) and  $E_i^*\tilde{W} \subseteq \tilde{W}$  for every i by construction.

Thus  $T\tilde{W}\subseteq \tilde{W},$  contradicting W beging irreducible.

## Chapter 5

# T-Modules of H(D, 2), I

#### Friday, January 29, 1993

Let  $\Gamma = (X, E)$  be a graph, A the adjacency matrix, and V the standard module over  $K = \mathbb{C}$ .

Fix a base  $x \in X$  and write  $E_I^* \equiv E_i^*(x)$ , and  $T \equiv T(x)$ .

Let W be an irreducible T-module with endpoint  $r := \min\{i \mid E_i^*W \neq 0\}$  and diameter  $d := |\{i \mid E_i^*W \neq 0\}| - 1.$ 

We have

$$\begin{split} E_i^* W &\neq 0 & r \leq i \leq r + d \\ &= 0 & 0 \leq i < r \text{ or } r + d < i \leq d(x). \end{split} \tag{5.1}$$

$$0 \le i < r \text{ or } r + d < i \le d(x).$$
 (5.2)

Claim:  $E_i^*AE_j^*W\neq 0$  if -j|=1 for  $r\leq i,j\leq r+d.$  (See Lemma 4.1.)

Suppose  $E_{j+1}^*AE_j^*W = 0$  for some j with  $r \leq j < r+d$ .

Observe that

$$\tilde{W} = E_r^* W + \cdot E_i^* W$$

is T-invariant with

$$0 \subsetneq \tilde{W} \subsetneq W.$$

Becase  $A\tilde{W}\subseteq \tilde{W}$  since  $AE_j^*W\subseteq E_{j-1}^*W+E_j^*W,$ 

$$E_k^* \tilde{W} \subseteq \tilde{W} \quad \text{for all} \ \ k,$$

we have  $T\tilde{W} \subseteq W$ .

Suppose  $E_{i-1}^* A E_i^* W = 0$  for some i with  $r \le i < r + d$ .

Similarly,

$$\tilde{W} = E_i^* W + \cdot E_{r+d}^*.W$$

is a T-module with  $0 \subseteq \tilde{W} \subseteq W$ .

**Definition 5.1.** Let  $\Gamma$ ,  $E_i^*$ , and T be as above. Irreducible T-modules W and W' are isomorphic whenever there is an isomorphism  $\sigma:W\to W'$  of vector spaces such that  $a\sigma=\sigma a$  for all  $a\in T$ .

Recall that the standard module V is an orthogonal direct sum of irreducible T-modules  $W_1 \oplus W_2 \oplus \cdots$ . Given W in this list, the multiplicity of W in V is

$$|\{j \mid W_i \simeq W\}|.$$

Remark. It is known that the multiplicity does not depend on the decomposition.

Now assume that  $\Gamma$  is the *D*-cube, H(D,2) with  $D \geq 1$ . Vew

$$X = \{a_1 \cdots a_D \mid a_i \in \{1, -1\}, 1 \le i \le D\},\tag{5.3}$$

$$E = \{xy \mid x, y \in X, \ x, y \ \text{differ in exactly 1 coordinate.} \}. \tag{5.4}$$

Find T-modules.

Claim: H(D,2) is bipartite with a partition  $X=X^+\cup X^-$ , where

$$X^+ = \{a_1 \cdots a_D \in X \mid \prod a_i > 0\} \tag{5.5}$$

$$X^- = \{a_1 \cdots a_D \in X \mid \prod a_i < 0\} \tag{5.6}$$

Observe: for all  $y, z \in X$ ,

 $\partial(y,z) = i \Leftrightarrow y,z$  differ in exactly in i coordinates with  $0 \le i \le D$ .

Here, the diameter of H(D,2) = D = d for all  $x \in X$ .

**Theorem 5.1.** Let  $\Gamma = H(D,2)$  be as above. Fix  $x \in X$ , and write  $E_i^* = E_i^*(x)$ , and T = T(x).

Let W be an irreducible T-module with endpoint r, and diameter d with  $0 \le r \le r + d \le D$ .

(i) W has a basis  $w_0, w_1, \dots, w_d$  with  $w_i \in E_{i+r}^*W$  for  $0 \le i \le d$ . With respect to which the matrix representing A is

$$\begin{pmatrix} 0 & d & 0 & \cdots & 0 & 0 & 0 \\ 1 & 0 & d-1 & \cdots & 0 & 0 & 0 \\ 0 & 2 & 0 & \cdots & 0 & 0 & 0 \\ 0 & 0 & 3 & \cdots & 0 & 0 & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ 0 & 0 & 0 & \cdots & 0 & 2 & 0 \\ 0 & 0 & 0 & \cdots & d-1 & 0 & 1 \\ 0 & 0 & 0 & \cdots & 0 & d & 0 \end{pmatrix}$$

(ii) \$ d=D - 2r\$. In particular,  $0 \le r \le D/2$ .

- (iii) Let W' denote an irreducible T-module with endpoint r'. Then W and W' are isomorphic as T-modules if and only if r = r'.
- (iv) The multiplicity of the irreducible T-module with endpoint r is

$$\binom{D}{r} - \binom{D}{r-1} \quad \text{if } 1 \le r \le R/2,$$

and 1 if r = 0.

*Proof.* Recall that  $\Gamma$  is vertex transitive. It is a Cayley graph.

Hence without loss of generality, we may assume that  $x = \underbrace{11 \cdots 1}^{D}$ .

Notation: Set  $\Omega = \{1, 2, \dots, D\}$ . For every subset  $S \subseteq \Omega$ , let

$$\hat{S} = a_1 \cdot a_d \in X \quad a_i = \begin{cases} -1 & \text{if } i \in S \\ 1 & \text{if } i \notin S. \end{cases}$$

In particular,  $emp\hat{t}yset = x$  and

$$|S| = i \Leftrightarrow \partial(x, \hat{S}) = i \Leftrightarrow \hat{S} \in E_i^* V.$$

For all  $S, T \subseteq \Omega$ , we say S covers T\$ if and only if  $S \supseteq T$  and |S| = |T| + 1.

Observe that  $\hat{S}, \hat{T}$  are adjacent in  $\Gamma$  if and only if either T coverse S or S coverr T.

Define the 'raising matrix'

$$R = \sum_{i=0}^{D} E_{i+1}^* A E_i^*.$$

Observe that

$$RE_i^*V \subseteq E_{i+1}^*V$$
 for  $0 \le i \le D$ , and  $E_{D+1}^*V = 0$ .

Indeed for any  $S \subseteq \Omega$  with |S| = i,

$$R\hat{S} = RE_i^* \hat{S} \tag{5.7}$$

$$=E_{i+1}^* A \hat{S} \tag{5.8}$$

$$= \sum_{T_1 \subseteq \Omega, S \text{ covers } T_1} E_{i+1}^* \widehat{T}_1 + \sum_{T \subseteq \Omega, T \text{ covers } S} E_{i+1}^* \widehat{T}$$
 (5.9)

$$= \sum_{T \subseteq \Omega, T \text{ covers } S} E_{i+1}^* \hat{T}. \tag{5.10}$$

Define the 'lowering matrix'

$$L = \sum_{i=0}^{D} E_{i-1}^* A E_i^*.$$

Observe that

$$LE_i^*V\subseteq E_{i-1V}^* \ \ \text{for} \ \ 0\leq i\leq D, \ \ \text{and} \ E_{-1}^*V=0.$$

Indeed for any  $S \subseteq \Omega$ ,

$$L\hat{S} = \sum_{T \subseteq \Omega, S \text{ covers } T} \hat{T}.$$

Observe that A = L + R.

For convenience, set

$$A^* = \sum_{i=0}^{D} (D - 2i)E_i^*.$$

Claim: The following hold.

- (a)  $LR RL = A^*$ .
- (b)  $A * L LA^* = 2L$ .
- (c) A\*R RA\* = -2R.

In particular  $\mathrm{Span}(R,L,A^*)$  is a 'representation of Lie algebra  $\mathrm{sl}_2(\mathbb{C}).$  Remark (Lie Algebra  $\mathrm{sl2}(\mathbf{C})).$ 

$$sl_2(\mathbb{C}) = \{ X \mid Mat(\mathbb{C} \mid tr(X) = 0 \}.$$

For  $X, Y \in sl_2(\mathbb{C})$ , define a binary operation [X, Y] = XY - YX.

$$A^* \sim \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad L \sim \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad R \sim \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

Then these satisfy the relations (a) - (c) above.

Proof of Claim. Apply both sides to  $\hat{S}$   $(S \subseteq \Omega)$ . Say |S| = i. Proof of (a):

$$(LR - RL)\hat{S} = L \left( \sum_{\substack{T \subseteq \Omega, T \text{ covers } S \\ (D-i \text{ of them})}} \hat{T} \right) - R \left( \sum_{\substack{U \subseteq \Omega, S \text{ covers } U \\ (i \text{ of them})}} \hat{T} \right)$$

$$= (D-i)\hat{S} + \sum_{\substack{V \subseteq \Omega, |V| = i, |S \cap V| = i-1}} \hat{V} - \left( i\hat{S} + \sum_{\substack{V \subseteq \Omega, |V| = i, |S \cap V| = i-1 \\ (5.12)}} \hat{V} \right)$$

$$(5.11)$$

$$= (D - 2i)\hat{S} \tag{5.13}$$

$$=A^*\hat{S}. (5.14)$$

 $Proof\ of\ (b)$ :

$$(A^*L - LA^*)\hat{S} = (D - 2(i-1))L\hat{S} - (D - 2i)L\hat{S} \quad \text{(since $L\hat{S} \in E^*_{i-1}V$)} \tag{5.15}$$

$$=2L\hat{S}. (5.16)$$

Proof of (c):

$$(A^*R - RA^*)\hat{S} = (D - 2(i+1))R\hat{S} - (D - 2i)R\hat{S} \quad \text{(since } R\hat{S} \in E^*_{i+1}V) \tag{5.17}$$

$$=2R\hat{S}. (5.18)$$

Let W be an irreducible T-module with endpoint r and diameter d  $(0 \le r \le r + d \le D)$ .

Proof of (i) and (ii):

Pick  $0 \neq w \in E_r^*W$ .

Claim: LRw = (D-2r)w.

Pf.

$$LRw = (A^* + RL)w \quad \text{(by Claim } (a)) \tag{5.19}$$

$$= A^* w \quad (Lw \in E_{r-1}^* W = 0) \tag{5.20}$$

$$(D-2r)w. (5.21)$$

Define

$$w_i = \frac{1}{i!} R^i w \in E^*_{r+i} W \quad (0 \le i \le d).$$

Then,

$$Rw_i = (i+1)w_{i+1} \quad (0 \le i \le d) \tag{5.22}$$

$$Rw_d = 0$$
 (by definition of  $d$ ) (5.23)

Claim:  $Lw_0 = 0$  and

$$Lw_i = (D - 2r - i + 1)w_{i-1}$$
  $(1 \le i \le d)$ .

*Pf.* We prove by induction on *i*. The case i=0 is trivial, and the case i=1 follows from above claim. Let  $i \ge 2$ ,

$$Lw_i = \frac{1}{i}LRw_{i-1} = \frac{1}{i}(A^* + RL)w_{i-1}$$
 (by Claim (a)) (5.24)

$$=\frac{1}{i}((D-2(r+i-1))w_{i-1}+(D-2r-(i-1)+1)Rw_{i-2} \quad (Rw_{i-2}=(i-1)w_{i-1}) \\ \qquad \qquad (5.26)$$

$$=\frac{1}{i}i(D-2r-i+1)w_{i-1} \tag{5.27}$$

$$= (D - 2r - i + 1)w_{i-1}. (5.28)$$

Claim:  $w_0, \dots, w_d$  is a basis for W.

 $P\!f\!.$  Let  $W'=\operatorname{Span}\{w_0,\dots,w_d\}.$  Then W' is R and L invariant. So it is A=R+L invariant.

Also it is  $E_i^*$ -invariant for every i.

Hence W' is a T-module.

Since W is irreducible, W' = W.

As  $w_i$ 's are orthogonal, they are linearly independent. Note that  $w_i \neq 0$  by the definition of d and Lemma 4.1 (iv).

Claim: d = D - 2r.

Pf. By (a),

$$0 = (LR - RL - A^*)w_d (5.29)$$

$$= 0 - (D - 2r - d + 1)Rw_{d-1} - (D - 2(r+d))w_d$$
 (5.30)

$$= -d(D-2r-d+1)w_d - (D-2(r+d))w_d \tag{5.31}$$

$$= (-dD + 2rd + d^2 - d - D + 2r + 2d)w_d (5.32)$$

$$= (d^2 + (2r - D + 1)d + 2r - D)w_d (5.33)$$

$$= (d+2r-D)(d+1)w_d. (5.34)$$

Hence d = D - 2r.

Therefore, with respect to a bais  $w_0, w_1, \dots, w_d, A = L + R, w_{-1} = w_{d+1} = 0$ ,

$$Lw_i = (d-i+1)w_{i-1}, \quad Rw_i = (i+1)w_{i+1}.$$

$$L = \begin{pmatrix} 0 & d & 0 & \cdots & 0 & 0 \\ 0 & 0 & d-1 & \cdots & 0 & 0 \\ & & \cdots & & \cdots & & \\ & & & & 0 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix}, \qquad R = \begin{pmatrix} 0 & 0 & 0 & \cdots & 0 & 0 \\ 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 2 & 0 & \cdots & & & \\ & & & & & 0 & 1 \\ 0 & 0 & 0 & \cdots & d & 0 \end{pmatrix}.$$

This completes the proof of (i) and (ii).
